Name of research ship:	r/v A. v. Humboldt	Cruise No. 44/04/08							
Dates of cruise:	4 May to 18 May 2004								
Operating authority :		Research Warnemuende 8111 Rostock. Germany.							
Particulars of ship:	r/v Alexander vonHu Nationality: Germany Overall length: Maximum draught: Gross tonnage:1270.5	64.23 metres 6.30 metres							
Ship's personnel:	Captain Gerhard Herz No. of crew 16	zig							
Scientific personnel:	Name and address of Prof. Dr. Bodo v. Bod Baltic Sea Research I Seestrasse 15 D 18 119 Rostock Germany Telephone: ++49-381 e-mail: bodo.bodung No. of scientists 12	dungen nstitute							
Geographical area:	15 – 23 °S, coast – 08	3 °E							

Brief description of cruise:

Investigating hydrographical and biogeographical characteristics and ichthyoplankton distribution of the Angola-Benguela Frontal Zone, monitoring training off Northern Namibia and Southern Angola.

Purpose of research :

To investigate hydrographical and biogeographical characteristics and ichthyoplankton distribution of the Angola-Benguela Frontal Zone; to differentiate ichthyoplankton populations south of , in and north of the front. To conduct training on monitoring lines from Cunene River to Namibe in general CTD operational methods and current measurements in the upper 1000 m, ichthyoplankton and zooplankton sampling in the upper 300 m, bottom samples for sediments and organisms. ethods by which samples were obtained included ship's weather station, satellite image, CTD, ADCP, Rosette, Multinet, Bongo Net, ROV, Multi corer, box corer, grab sampler, dredge,

Acknowledgements:

The scientists thank captain Herzig and his crew for their able support. Financial support of the cruise by IOW, MPI-Bremen, Ministry of Education of the Land Mecklenburg-Vorpommern, Federal ience and BCLME is greatly appreciated and BENEFIT and staff at its office in Swakopmund are thanked for logistical support. Scientific work and training took part in the framework of BENEFIT and GEF-BCLME.

Geoff Bailey and Quilanda Fidel are acknowledged for their contribution in collating and editing this abbreviated cruise report.

1. General Aim of Leg AHAB 8

The Angola-Benguela Frontal Zone (ABFZ) is the convergence zone between the Angola Current and the Benguela Current, separating tropical Angolan waters from the cool Benguela upwelling regime. Nearshore, the ABFZ separates the warm, highly saline southward-flowing Angola Current (AC, S>35.9) from the Benguela Upwelling (BU), generally with a small meridional temperature gradient. Farther offshore several fronts fan out southwestwards, separating the BU from the actual Benguela Current (BC, S<35.5) and northwestwards, separating the Angolan Gyre (AG) from the BC. The northward BC deflects towards the west and becomes the South Equatorial Current (SEC) farther north.

The ABFZ oscillates seasonally by some 3 degrees of latitude, and is on average centred at about 16°S, and is about 2 degrees of latitude wide near-shore and much broader offshore. This frontal zone is occasionally breached or displaced southwards, by warm Angolan water from the north. This can take the form of small intrusions, or major events. The latter, called Benguela Niños, have recently been shown to be the result of changes in wind stress patterns in the equatorial Atlantic Ocean.

Biological surveys crossing the ABFZ have been undertaken only recently. The present cruise is the third respective survey. The ABFZ is a zoogeographical boundary for mesopelagic fish, and should generally limit the distribution of tropical species towards the south, and that of cold water forms towards the north. However, the few studies made so far in near-shore waters did not have the necessary spatial and taxonomic resolution to investigate respective oceanographic-faunistic interdependencies. Fish larval abundances in near-shore waters have so far been found to be highest north of the ABFZ, and lowest south of it. It is furthermore hypothesized that a submergence of the Angola Current at the ABFZ might continues as a poleward slope undercurrent (SUC) southwards, and that cross-frontal transport of both water masses and fish larvae might also occur by filaments in the open ocean.

The survey was a multidisciplinary study continuing previous cooperation between the Department of Oceanography of the University of Cape Town, Institute for Baltic Research Warnemuende, National Marine Information and Research Centre, Swakopmund, German Centre for Marine Biodiversity Research, Hamburg and Instituto de Investigação Marinha now INIP (Instituto Nacional de Investigação Pesqueira / National Institute of Fisheries Research), Luanda.

The survey combined in situ CTD/O₂, ADCP oceanography, nutrient chemistry, chlorophyll and phytoplankton composition with ichthyoplankton studies from basic taxonomic work up to fisheries- related studies on faunistic composition, specific abundance, and vertical and horizontal spatial patterns. It was intended to sample 50 stations on four survey lines perpendicular to the coast to $8^{\circ}E$ – approximately 210 to 315 nautical miles long. The survey lines were intended to be chosen according to the actual location of the ABFZ derived from satellite images at the start of the survey. The northern and southern two lines would thus be representative of the Angolan and Benguela current regimes and the two central lines would cover the frontal system, proper.

The weather was fair; no time was lost due to rough seas. The sampling and work in the labs went smoothly, rare break-down of equipment was repaired by technicians and scientists on board.

2. General description of the cruise

On May 05 the ship took 14 teachers and students from Namibia just off Walvis Bay to demonstrate equipment – CTD, plankton nets, dredge, multicorer, grab –see Fig.1, station 'stud." Due to some problems with the cooling system the main cruise started a day later than planned originally. On May 07 at 14.00 hrs a station off Walvis Bay (station ADCP, Fig.1) was reached, where a hydrographic mooring was deployed and one hydrocast was taken in the framework of a Namibian-German cooperation within BENEFIT.

Thereafter the cruise continued, at approximately 01.00 hrs on May 8 the ichthyoplankton survey started on transect 1. Between transect 2 and 3 some benthic sampling was done crossing the Angola/Benguela Frontal Zone (ABFZ, stations BEO, see Fig. 1). The northernmost transect 4, was identical to the BENEFIT-Namibe-Monitoring-Line. The pelagic work on the transects was finished on May 17 at 06.30 hrs near the coast at station A47 slightly north of Namibe. At 3 sites directly off Namibe, benthos was sampled by grab and dredge. Cruise work ended on May 17 at 15.00 hrs. The ship sailed into Namibe in the morning of May 18.

3. Brief reports by the working groups and a first cursory look at the results. 3.1 Hydrography and ichthyoplankton survey

Hans-Christian John, Jennifer Veitch, Stefan Weinreben, Sven Hoffmann, Alice Chicunga, Wsaso Domingos & Fernando Gombo

Methods:

The team ran 4 transects normal to the isobaths, with 11 to 13 stations each (Fig. 1). The CTD measured depth, temperature, salinity, oxygen, chlorophyll a, turbidity, and phaeophytin down to 1000 dbar depth or 10 m above the bottom, if shallower than 1000m. Routinely, calibration work was carried out to standardize the temperature, salinity and oxygen probes on the CTD. Water samples for analysis of chlorophyll and nutrients and oxygen titration were handed over to the other groups from desired stations and depths.

All CTD stations were successful, except that we had a breakdown of the chlorophyll sensor between CTD-stations 13 and 15 and some repair work in between. There were no problems with the multinet. The multinet was towed obliquely at ships speeds 1.8 to 2.5 knots, and with winch speeds of generally 0.2 to 0.3 m/s. Expecting generally low fish larval abundances, the tows consequently exceeded somewhat the recommendations for quantitative fish larval surveys, in that they filtered 1.7 to 1.9 m³ water per 1 m depth. To avoid confusion arising from different depth ranges being sampled, the volume-data were transformed to filtered areas (Table 1) and fish larval abundances are expressed as N/ m² (Table 2). On the southern transect, the multinet sampled the overall depth range from 300 to 0 m in 5 steps: 300 - 200 m, 200 - 100 m, 100 - 50 m, 50 - 25 m and 25 - 0 m in order to sample the presumed poleward slope undercurrent depth. The three northern transects sampled 5 steps each as follows: 200 - 150 m, 150 - 100 m 100 - 50 m, 50 - 25 m and 25 - 0 m.

Step #	1	2	3	4	5
Depth	variable	variable	50-100m	50-25m	25-0m
Area filtered	1,66	1,93	1,84	1,69	1,70
SD	0,85	0,67	0,58	0,46	0,58
Ν	35	35	35	35	35

Table 1: Average areas filtered by the Multinet (MCN, based on the first 35 hauls only)

Working conditions to deploy and recover instruments were excellent. The possibility to maintain constant ships speed and low winch speed was occasionally limited, explaining the standard deviations up to 50 % particularly in the deepest stratum in Table 1.

Results:

Temperature and salinity

All four transects crossed the upwelling region zonally, as well as the other offshore elements of the frontal system (Fig. 2). The warm situation with weak winds prevailing before and during the cruise possibly caused a northward movement of the ABFZ. Available ships time did not permit addition of an extra transect north of the ABFZ in entirely Angolan Current water. Zonal surface temperature gradients were weaker than climatologically expected, but showed the increase from the inshore upwelled region westwards, and conformed with the common "fan-out" pattern.

Vertical sections of temperature (not shown) show the zonal deepening of isotherms towards offshore, but only inconspicuously the fronts proper. Conspicuous frontal structures appear in vertical sections of salinity (Figs 2 to 5), oxygen (Figs 7 -10) and chlorophyll (Figs 16-19). Besides the frontal structures, a high degree of smaller scale variability is shown by the above- mentioned parameters. This variability, perhaps linked with meridional transports described below, as well as by wind events before and during the cruise, needs future detailed analysis.

Geostrophic flow and oxygen

Meridional geostrophic flows were calculated from the hydrographic variables (pressure, temperature and salinity), relative to the surface flow (lacking, at present, a proper reference level of "no motion"). Equatorward flow prevailed on transect 1. Exceptions were a weak poleward flow east of approximately 8°E (at depths greater than 300m), a narrow (surface to \approx 60m) band of poleward flow centered at about 9.5°E, and another narrow, poleward jet at the shelf edge, which may be the common upwelling undercurrent. A subsurface oxygen minimum (<2ml/l) was situated at the shelf edge and deepens (300- 600m) offshore. This oxygen minimum is probably of local origin, as it does not correspond to a poleward flow that might have transported oxygen deficient water from the north. Farther offshore, west of 9°E and at depths of greater than about 300m, "patches" of oxygen minimum water occurred.. These coincide with the poleward flow noted there and are therefore likely to originate further north.

Transect 2 shows alternating bands of northward and southward flow. Two major northward currents were centered at approximately $9.2^{\circ}E$ and $10.5^{\circ}E$. West of $8.75^{\circ}E$, east of $10.75^{\circ}E$ and between the two northward flowing streams the flow reversed to polewards. On the shelf at approximately $11.7^{\circ}E$ a poleward jet occurred which was particularly intense at depths of greater than about 50m. Immediately west of this there was an equally strong northward current. A wedge of oxygen deficient (<2ml/l) water lay between about 300m and 700m narrowing from the continental shelf to approximately $8.5^{\circ}E$ at a depth of 450m. This wedge of oxygen- deficient water has been well-documented and has been shown to exist from the equator to approximately $20^{\circ}S$ off the African continent. The poleward jet on the continental shelf may have advected the relatively low oxygen concentration found there at depths greater than 70m.

The predominant geostrophic flow calculated for transect 3 was southward, but a relatively strong northward flow was found between 11°E and 10.3°E. Since the offshore part of transect 3 was north of the ABFZ (see salinity), this may be indicative of the presence of a southward-flowing AC. An opposing, northward flow existed near the continental shelf, at 11°E. This flow was most likely due to the extreme northward extent of a narrow coastal portion of the Benguela Upwelling zone. Oxygen deficient water exists in a zonal band from the base of the thermocline to a depth of approximately 700m. The base of this oxygen minimum layer was characterised by an upwards doming centered at about 9.75°E, which decreased in intensity towards the thermocline. Evaluation of transect 4 was not done, having made the final CTD casts on this transect just before reaching the port of Namibe.

Fish - and some phytoplankton

We encountered notable amounts of phytoplankton within the coastal upwelling zone and the inshore part of the front. Along the southern transect phytoplankton appeared to be reasonably healthy, and associated with jellyfish. Along transects 2 to 3 huge amounts of dead or decaying phytoplankton were caught, but jellyfish were less abundant and, if caught, smaller in size.

Few fish larvae were observed on Leg 1 whilst preserving the catch. Later microscopic analysis of samples confirmed that the two strata (25-50m and 50-100m) sampled at each of the stations on transect 1 had a low total catch and low abundance of fish larvae (Table 2). The relative maximum abundances, if representative, coincide with the ABFZ. Fish larvae there belonged exclusively to the mesopelagic community, and, when identifiable, to the Benguela fauna (*Symbolophorus boops, Bathypelagus greyae*), or species with an Atlantic-wide tropical/subtropical distribution (*Diogenichthys atlanticus*).

MCN-station	1	2	4	6	8	10
Longitude [°,]	13,04	12,48	12,10	11,13	9,55	8,40
N fish 25-50m	0	0	8	7	4	2
N fish 50-100m	0	1	0	3	0	6
N/1m² 25-50m	0,0	0,0	4,0	5,8	2,0	0,9
N/1m² 50-100m	0,0	0,3	0,0	1,9	0,0	2,1
minimum N/1m ²	0,0	0,3	4,0	7,7	2,0	3,0

Table 2: The total catch and abundance of fish larvae in the thermocline-strata 100 - 25 m depth in 6 selected stations from transect 1

During preservation of samples from transects 2 to 4 towards the north, increasingly larger numbers of fishes were visible in the front samples, and also in the adjacent open ocean. Transect 3 yielded among the decaying phytoplankton larvae of coastal fish species like sardine and horse mackerel. Distinctly tropical oceanic epipelagic to mesopelagic species were first observed at the 6 westernmost stations of transect 4, of which the fourth one (MCN-haul #39) revealed a distinctly faunistic influence of the Angolan Gyre (the East Atlantic Equatorial subspecies of *Vinciguerria nimbaria* occurred in numbers, larval *Hygophum macrochir* was also present).

3.2 Nutrients and oxygen titrations Bodo v. Bodungen & Francisco de Almeida

Methods:

Samples for nutrients were taken from CTD water bottles at 3 stations on transect 1, at 5 stations on transects 2 and 3 and 9 stations on transect 4 (see Fig. 1). Samples were analysed for dissolved inorganic phosphorus as phosphate (PO₄), silicon as silicate (SiO₄) and nitrogen in the form of nitrate (NO₃), nitrite (NO₂) and (NH₄) ammonium according to standard procedures described in the JGOFS-protocols and Grasshoff (1983). Oxygen were taken for Winkler titration from each station from selected depths to cover different water masses and gradients. Titration values were used to calibrate the oxygen sensor on the CTD, which worked perfectly, thus Figs 7-10 are from continuous profiling with the CTD probe.

Figs 11-15 shows surface distributions of the nutrient in the ABFZ and vertical distribution on the 4 transects, for gridding the data kriging was used. Density of the measurements is low in parts. Linear interpolation of the data and graphs for vertical distributions at individual stations will be applied later on. Nitrite and ammonium results are not depicted.

Cursory look at the results:

On transect 1 the upper 30 to 40 m of water are particularly low in SiO₄ (0.8 – 3.01 μ mol/l), indicating a previous strong growth of diatoms. Nitrate and phosphorus are more depleted offshore than nearshore with nitrate close to detection limit between 10 to 8°E. Deeper water concentrations reflected the different water bodies such as the BU, poleward undercurrent, BC and South Atlantic Gyre water (see also 3.1).

Transect 2 revealed similar low SiO₄ values, whereas much higher values for PO₄ and NO₃ (>2 and >30 μ mol/L) were found in the upper water column. On transect 3 the strong nearshore to offshore gradients were found between 11.2 to and 10.8°E. This also holds true for transect 4 but with a different zonal distribution. On transect 4, PO₄ shows some distinct features from surface to 300m water depth which needs further analysis.

The northern transects showed surprisingly high nutrient concentration in nearshore waters, which are higher than on the 2 southern transects and extend further offshore. Nutrient concentrations below 100m appear to be in accordance with the respective hydrography, however sampling was too sparse to allow more detailed analysis.

A striking difference between the northern and the southern transects is evident from the nitrate deficit or N*-values which are much more negative (-5 to -10) south of the front thus indicating considerable denitrification and excess of phosphorus, which could be a competitive advantage for the growth of blue-green algae. Considerable amounts of phycoerithrin were detected by the fluorescence probe on the CTD. This probe was not calibrated by discrete samples but this phenomenon may be worthwhile to follow up. On transect 4 in the north, N* was positive (> 3) in coastal waters and changed to negative values (-4) to the open ocean. The distribution of N*-values in relation to the redox gradients in the water column should be more intensively investigated.

Oxygen distribution is briefly described in 3.1, however a special situation should be mentioned here. Between transect 2 and 3 off the Cunene region some stations were sampled for benthos after CTD profiles were taken (see stations prefixed by BEO in Fig.1). Low oxygen values of $<1.8 \text{ mlO}_2/\text{L}$ in surface water and $<0.5 \text{ mlO}_2/\text{L}$ in bottom waters (water depth between 28 and 60m) was encountered from station BEO 1 to station 25. However at station 27 and 24 near bottom oxygen depletion was also found but the upper water column showed values of $>3.8 \text{ mlO}_2/l$. The oxygen- depleted water at the surface at stations BEO 1 - 25 must have been caused by a very local event of upwelling of oxygen depleted water, which was observed to be black at the surface. The zooplankton net was clogged with black phytoplankton. Discrete phytoplankton samples were taken at stations 25 to 27 and later microscopic analysis will reveal the composition of an obviously huge phytoplankton bloom (see also 3.3). A brief look at the netsamples showed that the large diatom *Coscinodiscus* (>300µ, see photos below) predominated and a few *Thalassiosira* spp. occurred, mostly in poor shape. Decay of this biomass was most likely in full operation as the highest ammonium and nitrite values (>1.5 µmol/L) of the cruise were found in surface waters of this area.

3.3 Phytoplankton and Chorophyll

Domingos da Silva Neto, Stefan Weinreben&Bodo v. Bodungen

Factors driving primary production include the availability of nutrients. Environmental changes affecting the distribution and dynamics of phytoplankton biomass exert an important influence on spawning success and the recruitment of juveniles into the fishery, and consequently, on fish stocks.. On the other hand, dissolved oxygen concentrations can be a complementary factor governing the distribution of fish stocks.

Available information on phytoplankton dynamics and distribution in the northern part of the Benguela Current, the Angola-Benguela Frontal Zone (ABFZ) and boundary between Angolan and Namibian waters is scarce.

This survey (AHAB Leg 8) was carried out from 22° S to 15° S and from the coastal zone to 8° E in order to contribute to an improvement of knowledge about the larval distribution in the northern Benguela Current / ABFZ and to discuss the influence of tropical waters of Angola Current origin on this area.

Methods:

Samples were collected at practically every second station offshore and more frequently near the coastal zone. For the Namibe Monitoring Line (NML) samples were taken for both chlorophyll and phytoplankton analyses, along the entire line.

Samples were collected on board R/V Humboldt at three to six depths at 27 CTDstations, in the range of low and higher values indicated on the CTD fluorescence trace usually between 0-60m. Values of fluorescence obtained from the measurement of chl *a* in bottle samples were used for the establishment of correlations with values obtained by the CTD fluorometer.

For each depth, 200-500 ml water was filtered in laboratory conditions through a Whatman (25 mm ø) GF/F filter under low vacuum (suction pressure ~ 200 mbar). The moist filters were folded by means of tweezers and they were placed in labelled tubes and stored dark in 10 ml. of 96 % ethanol extractor. After extraction, chl *a* and phaeopigment concentrations were determined according to the fluorescence reaction of chl *a* measured on a Turner 10-AU fluorometer. The values obtained for chl *a* and phaeopigments (phaeo) were calculated according to Edler (1979), HELCOM (1988) and JGOFS (1993).

For further taxonomic analyses, a sub-sample from each depth of the 24 surveyed stations was fixed with 2 % formaldehyde. Generally sampling was accompanied by measurements of water clarity and other physical and chemical parameters.

Preliminary results and prospectives:

The concentration of chl *a* in the northern Benguela was generally very low in Namibian waters, but much higher in the Angolan waters, particularly along the Namibe Monitoring Line. Here values at 0-20 m varied between 1.61 and 4.08 mg m⁻³ (see stations 50-55, along 15° S between 11° 17` and 12° 07`E). Particularly high values of chl *a* were found on the coastal zone of the Cunene River Transect (see stations 32 and 33; 17° 00`S; 11° 41`-11° 39`E). Values here reached a maximum concentration of 31.62 mg m⁻³, suggesting the occurrence of an algal bloom. This can be accompanied by death of fish, invertebrates and sea birds (Steidinger *et al.* 1981). The bloom might have been caused by nutrient input from both upwelling and the Cunene river. The values of dissolved oxygen in the water column can also be used for a future complementary analysis of the possible role of microalgal organisms on the distribution of ichthyo / zooplankton.

The correlation between the values displayed by the CTD fluorometer and chl a in calibration samples was very low ($r^2 = 0.32$). However, this can be improved as correlations should be done separately for the coastal and oceanic areas. The distribution of chlorophyll presented in Figs 16-19 is taken directly from the probe.

3.4 Macrozoobenthos

Michael L. Zettler&Catherine Isibore

Methods:

Benthic samples were taken with a 0.1 m² van Veen grab (Fig. 20, left). Due to sediment conditions, grabs of different weights were used. Three (or two, seldom only 1) replicates of grab samples were carried out at each station (Table 3). Additionally sometimes a dredge haul (net mesh size 5 mm) was taken in order to obtain mobile or rare species. All samples were sieved through a 1-mm screen and animals were preserved in the field with 4% formaldehyde. An underwater video-system was used at selected locations for the characterisation of the habitat i.e., assessment of sediment structure, species on the sediment surface and current (Fig. 20, right). The salinity and temperature of near bottom waters were measured by ship-based CTD-sensor and the oxygen content by titration according to the Winkler method. Altogether 13 stations in water depths between 28 and 340 m were sampled.

 Table 3: Stations sampled for macrozoobenthos during AHAB-8
 Image: Comparison of the same state of the same st

Fig. 21 : The macro-zoobenthos was sampled by a 0.1 m^2 van Veen grab (left). For imaging and assessing the underwater habitat a ROV was used at some stations (right).

Preliminary results:

The 29 replicates and the 7 dredge samples have not yet been analysed. Both subantarctic and subtropical taxonomical groups are to be expected in the waters off Namibia and Angola. Due to the enormous effort to learn the taxonomy of macrozoobenthos of these waters we decided to write a proposal to the DFG. Together with sampling stations from the AHAB-9 survey 55 replicates and 11 dredge haul samples have to be analysed.

The dominant taxonomical groups observed during onboard examination of the samples were the echinoderms, molluscs and cnidarians. Representatives were found from all other groups as well. The warmer waters of the north (see Table 3) were more biodiverse and groups like crustaceans, polychaetes and sponges became more dominant. Other taxa found in the samples included brachiopods.

Fig. 21: Sea fans (left) and brittle stars (right) were found often within the grab samples during AHAB-8.

During our benthic sampling we observed the tropical East Atlantic coastal snake eel *Dalophis boulengeri* and in cooperation with Dr. Christian John (Hamburg) noteworthy results in terms of fish biology were published recently (John & Zettler 2005).

Appendix 2: Location of metadata, data and samples from Leg 8

Parameters collected	German contact	Local contact	Samples / data
Physical Ocng - T,S, ADCP	Stefan Weinreben IOW, Warnemuende	Fernando Gombo (Namibe)	CD was provided and put onto .
Chemical Ocng - Oxygen, nutrients	Bodo von Bodungen IOW, Warnemuende	Francisco de Almeida (Luanda)	the Angolan databank
Remote sensing data	Herbert Siegel? IOW, Warnemuende	n/a	n/a
Ships meteorological data	Bodo von Bodungen	n/a	n/a
Chl a / pigment samples	Bodo von Bodungen	Domingos da Silva (Luanda)	
Phytoplankton samples	Bodo von Bodungen	Domingos da Silva (Luanda) / J. Muai, S. Silva and I. Rangel	Samples from 28 stations
Zooplankton samples	H.C. John, Sven Hoffmann Senckenberg Univ. Hamburg	Alice Chicunga (Namibe) Duplicate set to Domingas Paim (Luanda)	6 stations from Namibe M.L. Identification to finish July 06
Ichthyoplankton samples	H.C. John, Sven Hoffmann Data flagged until published . Samples, data available freely soon.	Wasaso Domingos (Luanda) Anja Kreiner, NatMIRC Namibia	6 stations from Namibe M.L. Identification to finish July 06
Sediment samples Benthos samples	Michael Zettler IOW, Warnemuende	Duplicate set given to Lia Neto Catherine Isibor, GCLME Nigeria	Occasional samples taken No local replicate set in Angola
